

## Naval Design

Assessing the human role  
in the early design phase

**M**any navy new building projects face a double challenge; the variety and complexity of operations are increasing, while at the same time, a reduction in manning is a prerequisite in order to lower building and operational costs. Therefore, it is important to identify the required number and type of crew and the supporting systems in the concept phase.

For a long time the use of weapons and platform systems have relied on a high degree of integrated, multi-sensor data processing and decision support systems. These systems are embedded in a concept of operation (CONOPS) and encompass an appropriate command and control structure, effective communication capabilities & protocols and suitable man-machine interfaces.

Nowadays, the main function of a navy vessel is to offer a stable ship platform to facilitate a myriad of operations for both weapon and small platform(s) deployment. Given the increasing relevance of this latter type of operations, a CONOPS approach is useful. This includes matching functionalities with different levels of automation and manning in the concept phase. To this end simulation and full-mission simulators are used. The first assesses the known physical criteria (for instance motion and signature characteristics) and the latter defines the human aspects and mental requirements during interactive simulations. Many man-machine interactions are defined in this simulator phase.

Simulations require the accurate modeling of the motion and response characteristics of all platforms involved and

potential interactions with other platforms (incl. air). Additionally, the prediction of vessel performance requires online measurement and fast assessment of the environment. Typical examples of platform related concept of operations using full-mission simulations are lifting (launch & recovery), docking, helicopter

landing, evasive actions (torpedo threat), replenishment at sea (or other sea basing) and emergency responses (fire, flooding, NBC attacks). Concerning the manning requirements and their competences, an early use of simulators identifies the level of automation, as well as the need for advisory systems, team interaction

protocols and education. In summary, during the concept design of advanced vessels, full mission simulators are essential to analyze the operational tasks and team interactions, to identify the required level of automation and decision support, and finally to establish the necessary training programs.

### About the Author

Johan de Jong is Manager International Cooperation at MARIN, the Maritime Research Institute Netherlands. MARIN offers simulation, model testing, full-scale measurements and training programmes, to the shipbuilding and offshore industry and governments.

## GET A TIGHTER GRIP ON MAINTENANCE COSTS

### COMPAC FOR LIFE

- Reduce operational costs
- Eliminate aft seal problems
- Eliminate emergency docking
- Fewer components
- Zero environmental impact
- Polar Code compliant
- Meets US VGP requirements
- Over 2000 ship references

**GUARANTEED FOR 15 YEARS**

Eliminate costly oil-lubricated seal maintenance with a seawater-lubricated COMPAC propeller shaft system
